problem3

1. We used bound functions because buttons only take functions without arguments as a value for a command which was troublesome because our interface was a class and those functions have a parameter self. However, a way to fix this was by bounding the function to the self rather than sending it as an argument.
2. I would create a global constant of our class, then create a global function or functions in the module and place in that function as the command for the buttons. This global function would trigger functions inside our interface object that is inside our global constant whenever the global function gets called by the button.
